SUMMARY ANALYSIS

08:15 AM Friday, 6th February 2026

Gender: Male Age: 6 Height: 176.00 cm Weight: 100.00 kg

HYDRATION SCORE

56.5% READ ALERT

[Hydration ALERT. Please read] The CSR ratio is higher than ideal. You are dehydrated. Both Carbs and the salt number are over ideal. And the salt is higher compared to the Carb result for an ideal ratio. Reduce all Salt in foods or fluids to balance the ratio. Correctly Rehydrate by following the suggested water intake first, then balance the CSR ratio.

Feb 3, 2026 — Feb 6, 2026

Recommendations to consider:

- Improve Hydration.
(Measured Water Bins showing markers in litres. The amount used is recorded exactly before refilled.)
- Eventually offer filtered water system.)
- Excess “food” being reduced according to numbers and therefore food is more likely to be utilised)
- Carefully lower pH. where necessary to below 8 above 7.
- Carefully lower carbs to 4 (reduced from avg 6 and highs of 9) Then increased 24hrs B4 race
- Consideration for cause and effect for each dietary component, including timing of foods and fluids
- No Feed ingredient change, just more precise on measurements and dosage.
- Focus 2 weeks on upcoming events. At least 1 test a day 2 weeks out and 2 tests a day 4-5 prior to event. Slight modifications with Matt and Nicks approval

The Future:

- Keep strict dietary records. A movement towards exact measured dosage of all foods and supplements.
- Combine all data with other professionals
- Eventually Go back to yearlings and 2yr olds with potential.
This is a building program and the healthier the upbringing and precise monitoring the better results all round.
- Build a system for exact data Feedback loop. Stable Manager, Jockey, times. Numbers
- LOOK for KPI's in results compared to Urine and Saliva Analysis, Bloods, Heart Health Data, Race and Trial Times, Team Intuition and Comments

HISTORY

09:09 AM 11/02/2026	64.3%	5.4	67.4%	8	52%	7	82%	26.2	59.6%	-	-	-

A focus on:

- **Current Performance Metrics:** An overview of the Health Scores (averaging 64%), Carbs (averaging 6.1), and pH levels (saliva and urine) from the provided tables.
- **Targeted Improvements:** Strategies like using measured water bins for hydration, reducing excess food based on data, and carefully lowering pH and carbs to reach proposed goal areas.,
- **Data Feedback Loop:** The future vision of combining analysis with feedback from the Stable Manager, Jockey, and race/trial times to monitor key performance indicators (KPIs).

Measured water bins improve hydration tracking by providing a precise method for monitoring fluid intake, which is a key focus for performance improvement in the program.

The implementation of these bins enhances tracking in the following ways:

- **Exact Volume Recording:** The bins feature **markers in liters**, allowing staff to record the exact amount of water used before the bin is refilled. This moves away from estimates toward **exact measured dosages** for all fluids.
- **Cause and Effect Analysis:** Precise measurements allow for a better understanding of the **cause and effect** of fluid intake timing and volume on the animal's performance and recovery.
- **Integration into Feedback Loops:** The hydration data is intended to be part of a comprehensive **data feedback loop**. By keeping strict records, this information can be compared against other **Key Performance Indicators (KPIs)**, such as urine and saliva analysis, heart health data, and race or trial times.
- **Precision Management:** This approach ensures that measurements and dosages are more precise without necessarily changing the ingredients of the feed or hydration system.

Ultimately, these bins are part of a building program designed to ensure that the more precise the monitoring, the better the overall results for the horses.

Targeting specific pH and carbohydrate goals is a central part of the **Precision Performance and Recovery** program, designed to optimize how a horse utilizes energy and recovers from exertion.

Carbohydrate Management and Energy Loading

The program aims to **lower carbohydrate levels during training to a target of 4**, a significant reduction from the current average of 6.1 and highs of 9.

- **Efficiency:** By reducing excess "food" based on these numbers, the remaining nutrients are **more likely to be utilized** by the horse rather than being wasted.
- **Race-Day Prep:** While the baseline is kept lower, carbs are strategically **increased 24 hours before a race**. This suggests a "loading" phase to ensure maximum available energy for the event after a period of precise maintenance.

pH Regulation for Optimal Health

The goal for pH levels (specifically urine) is to carefully lower them to **between 7 and 8**.

- **Current Status vs. Goal:** The sources show a current average urine pH of 8.2, indicating a need for downward adjustment to hit the "Proposed Goal Area".
- **Reducing Wasted Energy:** Monitoring these levels helps identify "Turbidity," which includes solids and sediment that represent **wasted energy**. Keeping pH within the target range helps ensure the horse's system is running cleanly and efficiently.

Measurable Performance Outcomes

The ultimate impact of hitting these pH and carb targets is tracked through **Key Performance Indicators (KPIs)**.

- **Correlation with Wins:** The program looks for correlations between "Best Scores" and actual racing success. For example, the horse **that** achieved a 1st-place finish on February 5th following a test that showed a urine pH of 7.96 and a carb level of 4.5—both very close to the program's targeted goals.
- **Data Feedback Loop:** These nutritional numbers are combined with data from stable managers, jockeys, and **race/trial times** to refine the approach. The philosophy is that more precise monitoring of these levels leads to "better results all round".

In summary, by using data to precisely manage dosages and measurements, the program reduces the amount of "waste" (turbidity) the horse produces, ensuring that **energy is directed toward performance** rather than being excreted.
